

Clinical Practice Guideline: Initial Management of Hypertension in Adults

Guideline ID: SYN-HTN-2026-002 **Version:** 2.0 **Effective Date:** October 2026 **Issuing Body:** Synthetic Guidelines Collaborative (for demonstration purposes)

1. Scope and Purpose

1.1 Clinical Condition

This guideline addresses the initial management of newly diagnosed essential hypertension in adults aged 18 years and older. It provides recommendations for initiating pharmacological therapy, lifestyle modifications, and monitoring plans based on blood pressure readings and relevant comorbidities.

1.2 Target Population

- 1 Adults (age 18+) with a new diagnosis of essential hypertension
- 1 Patients with or without comorbid type 2 diabetes mellitus
- 1 Patients with or without comorbid chronic kidney disease

1.3 Intended Users

This guideline is intended for primary care physicians, internists, nurse practitioners, and physician assistants involved in the outpatient management of hypertension.

1.4 Exclusions

This guideline does not address:

- 1 Secondary hypertension
- 1 Hypertensive emergencies or urgencies
- 1 Pediatric hypertension
- 1 Management of resistant hypertension
- 1 Pregnancy-related hypertension

2. Background

Hypertension is a leading modifiable risk factor for cardiovascular disease, stroke, and chronic kidney disease. Approximately 47% of adults in the United States have hypertension, defined as systolic blood pressure (SBP) greater than or equal to 130 mmHg or diastolic blood pressure (DBP) greater than or equal to 80 mmHg.

Early identification and treatment of hypertension significantly reduces the risk of adverse cardiovascular events. The presence of comorbid conditions such as diabetes mellitus and chronic kidney disease lowers the threshold at which pharmacological intervention is recommended, as these patients face compounded cardiovascular risk.

2.1 Blood Pressure Classification

Category	Systolic (mmHg)	Diastolic (mmHg)
Normal	< 120	< 80
Elevated	120-129	< 80
Stage 1 Hypertension	130-139	80-89
Stage 2 Hypertension	>= 140	>= 90

2.2 Key Comorbidities

Two comorbid conditions are particularly relevant to hypertension treatment decisions:

Type 2 Diabetes Mellitus. Patients with diabetes face accelerated vascular damage from hypertension. Current evidence supports a lower treatment threshold (SBP $\geq$ 130 mmHg) and more aggressive follow-up intervals in this population. ACE inhibitors such as lisinopril are preferred as first-line agents due to their renal protective effects.

Chronic Kidney Disease (CKD). Patients with CKD are at elevated risk for both cardiovascular events and progression of renal disease. As with diabetes, a lower treatment threshold is recommended. ACE inhibitors are preferred for their demonstrated renal protective benefits. More frequent laboratory monitoring is necessary to detect early changes in renal function.

3. Recommendations

3.1 Patient Assessment

All patients presenting with elevated blood pressure should undergo the following assessment:

- 1 Confirm blood pressure reading with at least two measurements on separate occasions
- 2 Review current medication list, including over-the-counter medications
- 3 Assess for the presence of type 2 diabetes mellitus
- 4 Assess for the presence of chronic kidney disease
- 5 Obtain baseline laboratory studies including a basic metabolic panel

3.2 Treatment Decision

The decision to initiate pharmacological therapy versus lifestyle modification alone is based on the patient's systolic blood pressure and the presence of comorbid conditions that increase cardiovascular risk.

Decision Table 1: Treatment Recommendation

The following table defines the recommended initial treatment action based on systolic blood pressure and comorbidity status:

Systolic BP (mmHg)	Has Diabetes	Has Kidney Disease	Action	Medication	Dose	Follow-up (weeks)
$\geq$ 140	No	No	Start medication	Lisinopril	10 mg daily	4
$\geq$ 130	Yes	No	Start medication	Lisinopril	10 mg daily	2
$\geq$ 130	No	Yes	Start medication	Lisinopril	10 mg daily	2
$\geq$ 130	Yes	Yes	Start medication	Lisinopril	10 mg daily	2
130-139	No	No	Lifestyle modification only	—	—	8
< 130	No	No	Lifestyle modification only	—	—	12
< 130	Yes	No	Lifestyle modification only	—	—	12
< 130	No	Yes	Lifestyle modification only	—	—	12

Key principles:

- 1 Patients with Stage 2 hypertension (SBP $\geq$ 140) should begin pharmacological therapy regardless of comorbidity status.
- 1 Patients with Stage 1 hypertension (SBP 130-139) AND diabetes or chronic kidney disease should begin pharmacological therapy due to elevated cardiovascular risk.

- 1 Patients with Stage 1 hypertension without high-risk comorbidities should attempt lifestyle modification for 8 weeks before reassessment.
- 1 Patients with elevated but sub-hypertensive blood pressure (SBP < 130) should focus on lifestyle modifications with follow-up in 12 weeks.

Lisinopril (an ACE inhibitor) is recommended as the first-line agent due to its well-established efficacy, renal protective effects, and favorable side effect profile.

3.3 Monitoring Plan

Once a treatment decision has been made, an appropriate monitoring plan should be established. Patients initiating medication therapy require laboratory monitoring to assess for potential adverse effects, particularly in patients with pre-existing kidney disease.

Decision Table 2: Monitoring Plan

The following table defines the recommended monitoring actions based on the treatment decision and comorbidity status:

Treatment Action	Has Kidney Disease	Lab Order	Lab Timing (weeks)
Start medication	Yes	Basic Metabolic Panel	2
Start medication	No	Basic Metabolic Panel	4
Lifestyle modification only	Yes	—	—
Lifestyle modification only	No	—	—

Key principles:

- 1 All patients starting ACE inhibitor therapy require a Basic Metabolic Panel (BMP) to monitor renal function and electrolytes.
- 1 Patients with chronic kidney disease require earlier laboratory follow-up (2 weeks) due to the higher risk of ACE inhibitor-related changes in renal function.
- 1 Patients on lifestyle modification alone do not require routine laboratory monitoring beyond standard preventive care.

3.4 Lifestyle Modification Recommendations

All patients with hypertension, regardless of whether pharmacological therapy is initiated, should receive counseling on the following lifestyle modifications:

- 1 **Dietary changes:** Adopt the DASH (Dietary Approaches to Stop Hypertension) diet, which emphasizes fruits, vegetables, whole grains, and low-fat dairy products while limiting saturated fat and sodium intake to less than 2,300 mg per day.
- 1 **Physical activity:** Engage in at least 150 minutes per week of moderate-intensity aerobic exercise, such as brisk walking, or 75 minutes per week of vigorous-intensity aerobic exercise.
- 1 **Weight management:** Achieve and maintain a healthy body weight (BMI 18.5-24.9 kg/m²). Even modest weight loss of 5-10% can significantly reduce blood pressure.
- 1 **Alcohol limitation:** Limit alcohol intake to no more than 2 drinks per day for men and 1 drink per day for women.
- 1 **Smoking cessation:** If applicable, provide smoking cessation counseling and resources.

3.5 Home Blood Pressure Monitoring

All patients in whom a treatment decision has been made under Table 1 should perform home blood pressure monitoring using a validated upper-arm device. Patients should take two readings one minute apart in the morning before medications and two readings one minute apart in the evening, on at least three and preferably seven consecutive days, and transmit their readings to the care team weekly through the patient portal, secure messaging, or telephone. The care team reviews the weekly average systolic and diastolic readings. A home average of 135/85 mmHg or higher is considered equivalent to an office reading of 140/90 mmHg. The responsible clinician should be notified when the weekly home average is 135/85 mmHg or higher, or exceeds a lower threshold set by the clinician for patients with diabetes or chronic kidney disease; this is a routine notification unless readings indicate a hypertensive crisis. Any single reading above 180/120 mmHg should be repeated after five minutes; if it remains above 180/120 mmHg the patient should contact the clinic the same day.

3.6 Follow-up Contact and Outreach

If a week passes without readings, a reminder should be sent to the patient. After three reminder attempts on different days without readings, the care team should contact the patient directly to identify barriers to monitoring. For patients starting or changing medication, the seven-day home average should be reviewed two to four weeks after the change, in addition to the laboratory follow-up in Table 2. Patients managed with lifestyle modification alone should have their home readings reviewed at the follow-up visit scheduled under Table 1.

4. Evidence Summary

The recommendations in this guideline are based on synthesis of the following evidence sources:

- 1 The Systolic Blood Pressure Intervention Trial (SPRINT) demonstrated that intensive blood pressure control (SBP < 120 mmHg) reduced cardiovascular events by 25% compared to standard control (SBP < 140 mmHg) in high-risk patients.
- 1 The ACCORD trial found that intensive blood pressure lowering in patients with type 2 diabetes reduced the risk of stroke but did not significantly reduce the composite cardiovascular endpoint compared to standard treatment.
- 1 Multiple meta-analyses confirm that ACE inhibitors reduce cardiovascular mortality and slow the progression of diabetic nephropathy and chronic kidney disease.
- 1 The DASH-Sodium trial demonstrated that combining the DASH diet with sodium restriction produces the largest reductions in blood pressure.

5. Implementation Considerations

5.1 Clinical Workflow Integration

This guideline is designed to be implemented through clinical decision support systems integrated into the electronic health record. Automated alerts should notify clinicians when a patient meets criteria for pharmacological intervention based on blood pressure readings and documented comorbidities.

5.2 Patient Engagement

Patients should be informed of their blood pressure status and involved in shared decision-making regarding treatment options. Patient education materials on lifestyle modifications should be provided at the time of diagnosis.

5.3 Quality Measures

The following quality measures are recommended for monitoring guideline adherence:

- 1 Percentage of patients with hypertension who have a blood pressure reading documented within the past 12 months

- 1 Percentage of patients meeting treatment initiation criteria who received appropriate pharmacological therapy within 30 days
- 1 Percentage of patients on ACE inhibitor therapy who received follow-up laboratory monitoring within the recommended timeframe
- 1 Percentage of patients performing home monitoring whose weekly readings were reviewed by the care team within seven days of submission
